

The temperature of the air inlet after the generator is high

What are the requirements for a gas turbine inlet temperature regulator?

The gas turbine inlet temperature regulator has strict requirements for the resistance of the air flow outside the tube. Generally, the operating resistance is required to be controlled below 150 Pa, which requires that the air flow speed should not be too high.

Does an inlet air cooling system improve power output and efficiency?

Still, the results indicate that the power output and efficiency of the gas turbine improved as long as the ambient temperature remained at their lower values. Because of this, the incorporation of an inlet air cooling system could mitigate the negative influence of high temperatures in tropical locations.

How does ambient temperature affect a gas turbine?

High ambient temperature decreases air density and consequently the air mass flow rate of the gas turbine. The consequence was a drop in both power output and thermal efficiency for gas-turbine-alone operation.

What temperature does an air inlet get?

If instead, you can direct the intake inlet to get "cold" ambient air at 20 °C (68 °F), the compressor will get the same volume of air at a density of 1.204 (kg/m³). This results in a 20.4% increase in compressor output.

How do I solve air inlet temperature problems?

Why does a gas turbine engine need a higher temperature?

The higher temperature allows for increased power and improved efficiency while adding higher cost for the direct cooling of the first turbine stage airfoils and other components. The performance of the gas turbine engine is dependent on the mass of air entering the engine.

What happens if air inlet temperature increases?

Based on Pulkrabek's study a 100 °C increase in inlet air temperature may result in a 10%-15% heat loss increase. It also increases the knocking possibility. Super and turbocharged type engines may encounter higher air inlet temperatures more than other engine types. So they need aftercooling systems to reduce the air temperature.

So at 18:24, the ambient capability = $(230 - 198.3) + 82.0 = 113.7$ °F. In this case, the generator set can continue to operate at full load with an outside air temperature of nearly 114 °F. When ...
